

Fall Forage Production by Winter Wheat Varieties in Oklahoma

2007

Production Technology 2008-1

April 2008

Vol. 20, No.1

Fall forage production by winter wheat is determined by several factors. Planting date and seeding rate are the two most influential factors that can be controlled by the farmer. Similarly, soil fertility plays a role in determining fall forage production by wheat. Environmental factors such as rainfall and temperature also play a heavy role in dictating how much fall forage is produced.

Wheat varieties differ in their ability to produce fall forage. To quantify these differences, the OSU small grains variety testing program measures fall forage production by wheat varieties. When evaluating these data it is important to remember that fall forage production is only part of the dual-purpose production system. First hollow stem, for example, will determine how long wheat can be grazed and has a large influence on the total amount of forage that might be harvested from a field.

Since occurrence of first hollow stem is so important, we also measure this phenological event at our Stillwater and El Reno locations (Table 1). Varieties differed by as much as 17 days in occurrence of first hollow stem in 2008. In 2007 we noted a delay in the onset of first hollow stem in our no-till plots at El Reno. While some differences were noted in 2008 too, the differences between conventional till and no-till were not as large as those recorded in 2007.

Table 1. Occurrence of first hollow stem (day of year) for winter wheat varieties sown in 2007 at El Reno and Stillwater, OK.

Seed Treatment

We have evaluated the effect of various seed treatments on grain yield before, but this year we evaluated the effect of a fungicide seed treatment, Charter® from BASF, on forage yield (Figure 1.). Fungicide-treated wheat seed generally produced more forage than non-treated wheat seed. The increase associated with fungicide-seed-treatment was not always statistically significant, and varied by location. We will evaluate similar treatments in the future to see if this trend holds over time.

Fall Forage Data

Fall forage production ranged from 1,550 to 2,570 lb/ac at Stillwater and 1,180 to 3,000 lb/ac at El Reno (Table 2.). Centered, Duster, Okfield and TAM 304 were the top forage producers at Stillwater. Top forage producers at El Reno conventional till included Deliver, Doans, Duster, Endurance, Fannin, Jackpot and Santa Fe. OK Bullet, Overley and Shocker were also in the top grouping in the El Reno no-till test.

Regardless of the location, there were several varieties that produced acceptable forage yield. Several years of testing fall forage production by wheat have revealed that there are always a few shining stars at the top and a few varieties at the bottom, but most varieties fall in the middle range and have adequate forage production. Poor forage production by a variety can generally be overcome by planting earlier or increasing seeding rate. It is also important to view forage production data in conjunction with yield performance after grazing.

Figure 1. Effect of 3.1 fl oz per 100 wt Charter® fungicide seed treatment on fall forage production by four winter wheat varieties at El Reno and Stillwater, OK in 2007

This is the second year that our fall forage production has been less in no-till than in conventional-till plots. No-till plots produced an average of 750 lb/ac less forage than conventional till plots in 2007. When two-year average data are evaluated (Table 3—next page) no-till plots average 870 lb/ac less forage than conventional-till plots. Anecdotal evidence suggests the decreased forage production might be offset by increased load-bearing strength of no-till fields. This increased load bearing strength decreases the amount of mud created by hoof traffic and decreases the maintenance energy required for cattle to move through the field. This hypothesis is not tested in our current experiment, however, and our data show thus far that fall forage production is lower in no-till systems than in conventional-till systems. We will continue to measure this parameter in coming years to see if the trend reverses.

About the OSU variety trials

The objective of the fall forage variety trials is to give producers an indication of the fall forage production ability of wheat varieties commonly grown throughout the state of Oklahoma. Similar to previous years, the forage trials are conducted under the umbrella of the Oklahoma State University winter wheat variety trials.

Nonirrigated fall forage variety trials were sown at El Reno and Stillwater, OK. All plots were sown at 120 lb/A. Conventional-till plots received 50 lb/ac of 18-46-0 in furrow at planting and no-till plots received 5 gal/A of 10-34-0 at planting. Additional location information is listed below.

Location information

	Planting date	Sampling date	pH	P	K
El Reno	9-17-07	12-06-07	4.7	116	264
Stillwater	9-14-08	12-04-07	5.7	50	369
